Clay mineral - Clay mineral - Chemical and physical properties: Depending on deficiency in the positive or negative charge balance (locally or overall) of mineral structures, clay minerals are able to adsorb certain cations and anions and retain them around the outside of the structural unit in an exchangeable state, generally without affecting the basic silicate structure.

Clay is a type of fine-grained natural soil material that contains hydrous aluminium phyllosilicates (clay minerals) that develops plasticity when wet. Geologic clay deposits are mostly composed of phyllosilicate minerals containing variable amounts of water trapped in the mineral structure. Clays are plastic due to particle size and geometry as well as water content, and become hard, brittle ...

Clay Particles Clay is the smallest soil particle. If blown up to an easily visible size, compared to other soil particles, a clay particle would be the size of a golf ball. Soils classified as clay typically contain zero to 45 percent sand, zero to 45 percent silt and 50 to 100 percent clay by volume.

In geology, the term clay includes all particles that are  $<2 \mu\text{m}$  (recall:  $1 \mu\text{m}$  or micron =  $10^{-6}$  meter), which is about the size of a Prokaryotic cell or  $1/100$  of a human hair, or the wavelength of infrared radiation). Sometimes the limit is reported at  $<4 \mu\text{m}$  (such as the engineering field).
